ADR 0007: Two services: Core (Django) and Vendor-admin (FastAPI)

Status	Accepted by the team (direction). **Amended by ADR 0008**, which moves commerce into Core
Date	2026-10-19, amended 2026-10-20
Related	`architecture.md`, `08-service-split.md`, ADR 0001, 0002, 0004, 0008

Context

ADR 0001 chose one modular monolith. The team then agreed that the vendor and admin side should be its own service in FastAPI. Reasons given or implied: vendors and admins have higher privilege and a different audience from shoppers; the vendor and admin work can be built by one track in parallel; a clean new codebase avoids the bug debt of today's backend.

Options

1. **One backend** (ADR 0001). Least operating work, strongest consistency, but the team did not want it.
2. **Two services:** the customer-facing Core and a vendor and admin service.
3. **Many small services** (vendors, catalog, orders, payments separately). Too much operating work for three engineers.

Decision

Option 2.

- **Core** (Django): customer identity, swipes, taste, feed, closets, embeddings, and (ADR 0008) cart, checkout, orders, stock and payments.
- **Vendor-admin service** (FastAPI): vendors, vendor and admin accounts, product authoring and price master, fulfilment screens, order read copy, commission settings, statements, admin tools.
- Separate databases (`shazlo_core`, `shazlo_vendor`) on one Postgres server; no cross-database access.
- Commands go over a synchronous internal API (vendor-admin to Core); facts go out as events through a transactional outbox, in both directions.
- Separate identities and token issuers; no shared users.

Consequences

- Vendor and admin can be deployed, secured and changed without touching Core; a customer token cannot reach vendor or admin data.
- Data is copied (the catalog copy in Core, the order copy in the vendor-admin database), so it is eventually consistent; reconciliation is required.
- More work before Oct 30: two services, a portal, contracts, two deploys. `architecture.md` section 14 gives the schedule and the cut order.

- ADR 0001's rules (layers, service and selector split, import-linter) apply **inside each service**. ADR 0004 changes: customers and vendors have separate token issuers; the portal uses vendor tokens from the start.
- ADR 0002 is narrowed: GraphQL (target) and REST (MVP) concern the **Core** app API only; the vendor-admin API is REST (FastAPI and OpenAPI).

Revisit when

- The team is too small to run two services reliably (merge the vendor-admin code back as a module; the module boundaries make that possible).
- Event volume or ordering needs a real message broker.
